The Public Cloud service is provided by all data centers using a Cloud Cluster Group, which lets customers create, use and manage virtual machines. The machines are managed from a Customer Admin Panel and a provisioning environment, both of which are accessed via a firewall-protected public network. The functionalities of the virtual machines of the Cloud Cluster Group are performed using a public network with access to public internet. The physical machines of the Cloud Cluster Group use a private network to communicate with each other and a storage network containing replicated disks.
